INTRODUCTION

INTRODUCTION

This document presents population projections to the year 2011 for each of Ontario's regional municipalities, counties and districts. The projections are based on the 1986 Census counts of population and use assumptions that reflect the latest trends in fertility, mortality and migration. The projections will be updated regularly in future to reflect changing information and continuing refinements to the forecast methodology.

These projections will be used throughout the Ontario Government for a variety of planning purposes. They are offered, "as is", for use by regions and counties that do not produce their own population forecasts, and as a reference tool for those that do. School boards, district health councils, and private sector companies and consultants are among the other users of these projections.

The first section of the document reproduces the highlights of the Ontario-level population projections that were published in the January 1989 edition of the *Demographic Bulletin.* These provincial-level projections are the foundation of this report. The forecast populations for the regions, counties and districts are derived by disaggregating the high, medium and low scenarios for the province as a whole.

The second part of the document presents an overview of the projection results. The third part provides detailed projection results for each of the regions, counties and districts. Given the volume of inputs required, it was not feasible to publish the entire set of assumptions for each area; users requiring additional information are invited to contact the Ministry at the address on the back cover.

The final section of the report is a brief account of the methodology used in preparing the projections. A number of points need to be emphasized in this respect:

1. *These projections are not to be construed as Government of Ontario "targets" for the areas in question.* They are mathematical calculations of what the future population might be, given alternative, plausible assumptions about future fertility, mortality and migration.

2. *Projections necessarily diminish in "certainty" the further into the future they are extended.* Migration is an especially complex phenomenon, and is very difficult to forecast with any degree of confidence. Most of the data in this report relate to a "reference", or most likely, population scenario, but high and low scenarios are also presented for each area. These scenarios can be interpreted as framing the probable range of the future population.

3. *These projections do not incorporate explicit assumptions about public policy choices relating to regional development, or about future infrastructure placement.* They are based on an extrapolation of past trends and relationships, modified, as appropriate, to reflect plausible changes in demographic variables and general economic conditions.

The Office for the Greater Toronto Area and the Greater Toronto Coordinating Committee, with assistance from the Regional Planning Commissioners, are commissioning a study of alternative approaches to projecting population, and will investigate the possibility of integrating "top-down" population modelling of the type reported in this document with "bottom-up" modelling based on micro-level assumptions about land use. The Ministry of Treasury and Economics looks forward to the successful conclusion of this project.

In early 1989, an "experimental" set of sub-provincial population projections was circulated for comment to all Ontario Government ministries, all regional and county governments, and selected municipalities in Northern Ontario. A number of meetings were subsequently held with officials from the local government sector.

As a result of these consultations, a number of changes in the assumptions were made to acknowledge the well-argued concerns of certain regions. The Office for the Greater Toronto Area assisted in the consultations with GTA officials, and helped secure the high degree of consistency that now exists between these projections and projections generated independently by GTA planning departments. The Ministry of Treasury and Economics thanks all those who supplied information and advice during the consultation stage leading to finalization of its projections.

HIGHLIGHTS OF THE PROVINCIAL PROJECTIONS

HIGHLIGHTS OF THE PROVINCIAL PROJECTIONS*

- The population of Ontario is projected to grow from 9.1 million at the June 1986 census to almost 11.9 million by June 2011.
- Under the low scenario, Ontario's population would be 11.0 million in 2011, while under the high scenario, it would reach 12.8 million.
- Annual population growth will fall over the forecast period. Although the rate of growth rose slightly to 1.8 per cent in census year 1987-88, it is expected to fall continuously to 1.0 per cent by 1996-97 and to below 1.0 per cent thereafter.
- As the baby boom generation passes through the prime childbearing ages, the number of births will continue to rise modestly from 134,000 in 1986-87 to 139,000 in 1990-91. Over the next fifteen years, the annual number of births will decline to less than 124,000 by 2005-06. Thereafter, the number of births will increase modestly as the children born during the baby boom echo reach the prime ages of family formation.
- Annual deaths will increase from 67,000 in 1986-87 to 89,000 in 2010-11.
- Net migration will add about 437,000 people to the population of Ontario between 1986-87 and 1990-91, accounting for 56 per cent of the total population increase. Net migration over the subsequent five years will be about one third lower, and will account for 47 per cent of the total population increase.
- Growth in the population aged 45-64 will be dramatic as the baby boom generation starts turning 45 in 1991. The 45-64 age group accounted for 20 per cent of the Ontario population in 1986, but will account for 28 per cent in 2011.
- In 2011, nearly one in every 6 Ontarians will be over 65. The 65-74 population will increase from 603,000 or 7 per cent of the total population in 1986, to 977,000 or 8 per cent of the total population in 2011. The over 75 population will more than double from 391,000 in 1986 to 874,000 in 2011.
- The median age for females will climb from 33.1 years in 1986 to 42.7 years by 2011; for males, the median age will rise from 31.4 to 39.7 years.

Note: Reference Scenario assumes medium fertility, mortality and migration. Low Scenario assumes low fertility, life expectancy and migration. High Scenario assumes high fertility, life expectancy and migration. Scenario 4 assumes medium fertility and mortality but low migration. Scenario 5 assumes medium fertility and mortality but high migration.

HIGHLIGHTS OF THE PROJECTIONS FOR REGIONAL MUNICIPALITIES, COUNTIES AND DISTRICTS

HIGHLIGHTS OF THE PROJECTIONS FOR REGIONAL MUNICIPALITIES, COUNTIES AND DISTRICTS

- The population of the **Greater Toronto Area** (comprising Metropolitan Toronto and the regions of Durham, York, Peel and Halton) is projected to grow from 3.7 million at the 1986 Census to 5.3 million by 2011, under the reference scenario. Its share of the total Ontario population will rise from 41.0 per cent in 1986 to 44.8 per cent in 2011.

- The 2011 population range for the GTA is 5.0 to 5.8 million.

- The **Metro Toronto** population is forecast to increase from 2.2 million in 1986 to 2.5 million by 2011 under medium assumptions and to 2.7 million under high assumptions. A population larger than this is unlikely to occur in the absence of dramatic increases in immigration to Canada and very deliberate policy changes in support of population concentration in the municipality.

- Population growth for Metro is projected to be higher than it was over the 1970s and early 1980s, and higher than in previous projections. This reflects a more optimistic view of the potential for population infilling on vacant land and on land converted from commercial and industrial purposes. It also reflects stabilization, and perhaps some increase, in average household size; the Baby Boomers have completed their departure from their parental homes, and the turnover of homes in the "older" suburbs from empty nesters to younger families has begun. High migration, affordability issues and transportation considerations may lead to increased "doubling up", the construction of more "in-law apartments", and more frequent renting of surplus rooms and basements, where permitted. (As indicated, no specific assumptions have been made about these factors.)

- Most areas surrounding the GTA (Simcoe, Dufferin, Wellington, Waterloo and Victoria) will continue to experience above average population growth as a result of their interaction with the GTA economy. The same holds true for counties near the Ottawa-Carleton Region, such as Prescott and Russell, and Lanark.

- The **Ottawa-Carleton Region** is projected to grow from 607,000 in 1986 to 776,000 in 2011. Growth rates for other major urban regions in Southern Ontario vary somewhat but tend to be close to the provincial average.

- The population of **Northern Ontario** is projected to remain essentially constant, increasing from 807,000 in 1986 to 822,000 by 2011.

- Slow or negative population growth in the North reflects declining fertility, a low share of international immigration, and a relatively large pool of youth with an above average propensity to out-migrate. Economic diversification will create jobs and slow out-migration, but this will be offset to some extent by continuing capital-for-labour substitution in much of the resource industry.

APPENDIX: METHODOLOGY AND ASSUMPTIONS

METHODOLOGY AND ASSUMPTIONS

The population projections in this document for Ontario regions, counties and districts were produced by "disaggregating" recently published projections for the province as a whole. The reference scenario of the sub-provincial projections corresponds to the reference scenario for Ontario, as do the high and low projections, respectively.

An expanded cohort survival approach is used, in which fertility, mortality and migration assumptions for each regional municipality, county and district (hereinafter "county" for simplicity) are indexed to the corresponding assumption at the provincial level. The structure of the model is such as to allow capture of essential regional differences in demographic variables. The assumptions themselves were made after reviewing broad historical data, and after considering likely social and economic trends of a general nature. The projections are NOT built up from local official plans, or locally prepared forecasts, and they do NOT embody specific, explicit assumptions about infrastructure placement or public policies relating to regional development.

The following discussion of the county projection methodology explains each demographic component in turn. Readers requiring further details of the approach are invited to contact the Ministry at the address on the back cover.

The Base Year

The "base" used in the projections is the 1986 Census count of population, by age and gender, for Ontario and each of its counties, adjusted for the underenumeration of the native population. The base was NOT adjusted for the general underenumeration in the Census.*

The projections for 1987 were compared with Statistics Canada's preliminary estimates for that year, and were found to be very close in all cases; in this respect, the projections base can be said to have been "updated" using the best information available on a uniform basis for all jurisdictions. Nevertheless, high net migration and housing starts in the last three years, combined with the census undercount problem, suggest that for some counties the projections base may still be below the "true" current population.

---

* See discussion in the *Demographic Bulletin*, January 1989.

Fertility

An approach to model fertility must meet three requirements:

1. It must recognize that fertility varies significantly from one part of the province to another. In 1986, the total fertility rate (TFR) ranged from a high of 2.6 in Kenora (53 per cent above the provincial average) to a low of 1.5 in Ottawa-Carleton (13 per cent below the provincial average).

2. It must recognize that the age structure of fertility also varies considerably from one area to another. In 1986, for example, women under 25 accounted for 41 per cent of births in Northern Ontario but only 24 per cent of births in Ottawa-Carleton; conversely, women over 35 accounted for 11 per cent of births in Ottawa-Carleton and only 5 per cent of births in the North. The structure of age-specific fertility rates interacts with the age distribution of the female population to determine the number of births, and must be modelled correctly if births are to be projected accurately.

3. It must avoid unnecessary "ratchet" effects between the last year of the actual data and the first year of assumed values. Significant discontinuities can sometimes occur when counties are grouped for the purpose of making assumptions.

Fertility is modelled as follows:

1. The provincial TFR for each future year is taken from the identified provincial level simulation. In the reference scenario, the TFR is held constant at 1.7 births per woman through to 2011, while in the high fertility scenario it increases linearly to a 2011 value of 2.1 and in the low fertility scenario decreases linearly to a 2011 value of 1.3. The age structure of fertility is held essentially constant at its 1986 pattern.

2. A TFR is then established for each county in each future year. An assumption matrix is created giving each county's TFR as a proportion of the provincial TFR for future years. The proportions are held constant for five-year intervals. For example, in the reference scenario, Algoma's TFR is assumed to be 105 per cent of the provincial average for years between 1986 and 1991, dropping to 101 per cent for years between 1991 and 1996. The values themselves are determined largely on the basis of extrapolation from historical data, with reference to trends in demographically and economically similar communities. As in the projections generally, the extrapolation is not rigidly statistical in nature. The TFR for a county is, then, the assumed proportion for the year in question multiplied by the provincial TFR for that year from the provincial control simulation. Alternate assumption matrices give other views about trends in county fertility relative to the provincial average.

3. The county TFRs are next disaggregated into age-specific fertility rates. Five "typical" age structure vectors were assumed, each giving the proportion of the TFR accounted for by women of a particular age. For example, in one vector, women under 25 account for 40 per cent of the TFR while another vector has them accounting for only 25 per cent. Each county is then assigned a vector to be used in the calculation, based on recent data. Most districts in the North are assigned the first vector mentioned here, but Sudbury and Thunder Bay, like most urban areas in the south, are assigned vectors with a higher modal age of fertility. The assignment of vectors can be changed in future years to capture trends in an area's age-specific fertility structure; it has been assumed that counties continue indefinitely with age-specific fertility structures similar to what they had in 1986 (i.e., they retain the same vectors).

4. To illustrate the fertility calculation, the number of births to 23 year old women in Algoma in 1993 would be the product of: (1) the number of such women; (2) the Provincial TFR for that year in the control scenario; (3) the Algoma proportion of TFR for that year; and (4) the proportion in the cell for 23 year old females in the vector assigned to Algoma. Total births in Algoma in 1993 would be the sum of all such calculations for 15-49 year old females.

Mortality

The sub-provincial modelling of mortality is broadly similar to that adopted for fertility. The modelling requirements established at the outset were:

1. There must be recognition of regional differences in mortality across the province. For example, in 1986, male life expectancy at birth in the North was 96.5 per cent of the provincial average (70.9 years vs 73.5 years).

2. There must be recognition that these differences in mortality vary by age and sex and are not simply uniform across the full spectrum of 182 age-specific death rates (91 male and 91 female).

3. There must be capacity to make independent assumptions, at the regional level, for differences in mortality between men and women. For example, the model must recognize that life expectancy at birth for Northern women is much closer to the provincial average than it is for Northern men.

Mortality is modelled as follows:

1. In the provincial control simulation, the age-sex specific death rates are assumed to decline linearly over future years to yield either low, medium or high gains in life expectancy. Under the three scenarios, only slight differences were assumed with regard to the male-female life expectancy gap.

2. Regional differences in mortality are evident from historical data. To model this, five mortality vectors were created. Each expresses each age-sex specific death rate as a proportion of the corresponding rate for the province as a whole. For example, the first vector may give the male infant mortality rate as 105 per cent of the provincial average, but the mortality rate for 45 year old males as 98 per cent.

3. Each county is then assigned the vector which most closely approximates its own mortality structure in recent years. Vector assignment can be changed for future five-year intervals to capture trends in mortality relative to the provincial average. For example, a county may be assigned a typically "rural" mortality vector up to 1996 and a more typically "urban" one thereafter. In all but a few cases, however, the reference scenario keeps the initial assignment constant into the future.

4. To illustrate the mortality calculation, the number of deaths among 54 year old females in Perth in 1997 would be the product of: (1) the number of such women; (2) the provincial mortality rate for such women in that year from the control simulation; and (3) the proportion for this age-sex group in the vector assigned to Perth for that year. Total deaths in Perth in 1997 would be the sum of 182 such age-sex specific calculations.

International Migration

1. The assumed number of international immigrants and emigrants per year is available from the control provincial simulation.

2. Each county is given its share of each migration stream, based largely on its share during recent years, but with some general account taken of projected economic performance in the county and the geographic area of which it is a part. The assumed shares can be varied at five-year intervals in the future. For example, Algoma may be assigned 3 per cent of the province's international immigrants and 2 per cent of its emigrants over the 1986-91 period, and 2 per cent and 1 per cent respectively over the 1991-96 period.

3. A county's net international migration in a year is, of course, the difference between the two products (shares multiplied by total provincial flows).

4. The age and sex structure assumed for every county's immigrants and emigrants is the same as that assumed for each of these flows at the provincial level. While there are in fact some differences in the age-sex composition of international migrants by county, the historical evidence is not strong enough to warrant unique assumptions for each county. In any event, the task of modelling this would be large relative to the small improvement that could be achieved in the accuracy of the projected age-sex distribution for each county.

Interprovincial Migration

Interprovincial migration to and from a county is modelled in exactly the same way as immigration and emigration. Historical information provides the basis for the assumed county shares of both the interprovincial inflow and interprovincial outflow in each year. The shares can again be varied at five-year intervals. The actual net number of migrants in a year is the difference between the two products (shares multiplied by total provincial flows from the control simulation). The provincial level age-sex distributions of the inflows and outflows, respectively, are used for all counties.

Intraprovincial Migration

Because of the sensitivity of the sub-provincial projections to the level and direction of inter-county migration, several approaches to modelling this component were investigated. The approach finally adopted works as follows:

1. For each county, an out-migration rate is assumed for each five-year period into the future. For example, it might be assumed that in each year between 1986 and 1991, Algoma will lose, on a gross basis, 3% of its population in the preceding year to other counties in Ontario; between 1991 and 1996 it might be assumed to lose 2%; and so forth. As with other assumptions, the assumed out-migration rates are developed after reviewing historical trends for individual counties and the geographic regions in which they are located, and after taking account, in general terms, of the short-term economic outlook. Out-migration rates are reduced by about 10% across the board starting in 1996 to reflect the aging of the Baby Boom generation.

2. The summation of the out-migrants in a given year, determined above, constitutes a "pool" which now has to be distributed as in-migrants to each county. For this purpose, each county is given an assumed share of the total pool, with the assigned shares, like the assigned out-migration rates, being variable at five-year intervals into the future. The assumed shares are likewise based largely on historical values. The shares sum to 100 per cent.

3. A county's net intraprovincial migration in a year is, of course, the difference between its out-migrants and its in-migrants.

4. A single age-sex structure is used to distribute the net number of intraprovincial migrants. This structure is different from both the overall age-sex structure for the province, and the structures used for international and interprovincial migration. Moreover, the same structure is assumed for all future years, though there is capacity to vary this if desired. An earlier comment can be repeated here: while there are some known differences in the age-related patterns of internal migration (relatively more elderly migrants into Haliburton, Muskoka and Victoria, for example), the payoff of trying to model this is small relative to the quality of the historical data, the sheer volume of the assumptions to be defended, and the technical difficulty involved.

High and Low Scenarios

The reference county population projections given in this report correspond to the reference provincial projection. The high projections correspond to the provincial scenario that combines high fertility, high life expectancy and high migration, while the low projections correspond to the provincial scenario that combines low assumptions for each variable.

The high and low county projections do not incorporate specific assumptions relating distributional variables to levels variables. That is, a county's total fertility rate, as a proportion of the provincial average, remains the same in the high, medium and low scenarios; its *shares* of international and interprovincial migration flows also remain the same, as does its share of the intraprovincial migrant pool. (The *size* of the internal migrant pool does vary, with out-migration rates being 10 per cent higher in the high scenario and 10 per cent lower in the low scenario; the approach is thus congruent with that of international and interprovincial migration where the volume, but not the shares, changes.)

Theoretically, changes in levels probably involve changes in intercounty relationships. For example, Metro likely gets a different *share* of immigrants when total immigration to Ontario is high than it does when immigration is low; and suburban areas may have a higher TFR relative to the provincial average when and if fertility rises. However, lack of empirical data limits the feasibility of taking account of these types of considerations.

This conceptual issue aside, the high and low projections can be taken as establishing plausible upper and lower limits on the future population; by 2011, the high projections average about 8 per cent above the most likely, or reference case, scenario, while the low projections average about 7 per cent less.

Final Adjustments

Despite the fact that fertility and mortality are indexed to the provincial average, the sum of births, and the sum of deaths, taken across the 49 counties do not add exactly to the values shown in the corresponding provincial control solution. An iterative procedure is used to resolve this problem, with the initial county assumptions modified slightly each time until an acceptable degree of conformity is achieved in the results. In addition, some fine-tuning of assumptions is required to ensure that for each county the components of population change in the early years of the forecast period are not implausibly different from the most recent recorded values. As a result of this iteration, the sum of the projected populations for the 49 counties conforms very closely to the independently generated figure in the provincial control simulation.

"Experimental" projections produced using this methodology were circulated to Ontario Government ministries, regional and county governments, and several municipalities in Northern Ontario. As a result of subsequent consultations and advice, further modest adjustments were made to the assumptions, yielding the final projections published in this document.

TOTAL FERTILITY RATE OF COUNTIES/DISTRICTS/REGIONAL MUNICIPALITIES AS A PER CENT OF PROVINCIAL TFR, 1981, 1986, 1986-2011.
